Acute Scrotal Pain
Clinical Pathway
This pathway is intended as a guide for physicians, physician assistants, nurse practitioners and other healthcare providers. It should be adapted to the care of specific patient based on the patient’s individualized circumstances and the practitioner’s professional judgment.
Rationale:

This clinical pathway was developed by a consensus group of JHACH physicians, advanced practice providers, nurses and pharmacists to standardize the management of children undergoing triage with Acute Scrotal Pain. It addresses the following clinical questions or problems:
1. When to evaluate for testicular torsion
2. When to consider admission for further evaluation and surgical intervention
3. When to consult Pediatric Urology or Pediatric Surgery
4. When to consider ruling out alternative diagnosis

Background:

The spectrum of conditions that affect the scrotum and its contents ranges from incidental findings to pathologic causes that require expeditious diagnosis and treatment (e.g., testicular torsion, testicular cancer). The most common causes of acute scrotal pain in children and adolescents include testicular torsion, torsion of the appendix testis, and epididymitis (table 1). In one review of 238 consecutive boys, ages 0 to 19 years, who presented with acute scrotal pain to a children's hospital over a two-year period, 16 percent had testicular torsion, 46 percent had torsion of the appendix testis, and 35 percent had epididymitis (Lewis et al., 1995).

Testicular torsion is the most important and potentially serious of the acute processes affecting the scrotal contents because it may result in the loss of the testicle. Intravaginal torsion results from inadequate fixation of the testis to the tunica vaginalis through the gubernaculum testis. The most common abnormality associated with testicular torsion is known as the "bell clapper" deformity where the testicle lacks the normal attachment to the tunica vaginalis (permitting increased mobility) and rests transversely within the scrotum. The bell clapper deformity may be bilateral and predisposes to testicular torsion.

If fixation of the lower pole of the testis to the tunica vaginalis is insufficiently broad-based or absent, the testis may torque (twist) on the spermatic cord. The twisting of the spermatic cord within the tunica vaginalis causes venous compression and subsequent edema of the testicle and cord with ultimate ischemia of the testicle caused by arterial occlusion.

Testicular torsion has two peak incidences: a small one in the neonatal period and a large one during puberty, but it can occur at any age. The incidence is estimated to be 1 in 4000 in males younger than 25 years old. Approximately 65 percent of cases occur in boys between the ages of 12 and 18 years (Bašković et al., 2019). The increased incidence during adolescence is thought to be secondary to the increasing weight of the testes during pubertal development.
Diagnosis

The diagnosis of testicular torsion can be made clinically. Thus, when clinical findings are strongly suggestive for testicular torsion (e.g., acute onset of severe testicular pain in association with nausea or vomiting with findings of absent cremasteric reflex, testicular tenderness with swelling and high-riding or transverse position), the clinician should promptly consult a surgeon with pediatric urologic expertise to evaluate the patient and plan regarding operative exploration and repair.

Observational studies suggest that clinical findings may reliably identify testicular torsion and can be used to make decisions regarding Doppler ultrasound imaging and surgical consultation. A single-institution prospective study of 338 children with an acute scrotum (Barbosa et al., 2013), resulted in the creation of the TWIST (Testicular Workup for Ischemia and Suspected Torsion) score for testicular torsion:

- Nausea or vomiting: 1 point
- Testicular swelling: 2 points
- Hard testis on palpation: 2 points
- High-riding testis: 1 point
- Absent cremasteric reflex: 1 point

During derivation, a score ≥5 diagnosed testicular torsion with 76% sensitivity, 100% specificity, and 100% positive predictive value (PPV) (prevalence of torsion, 15% → what does this mean in this context?). A score ≤2 excluded testicular torsion with a 100% sensitivity, 82% specificity, and a 100% negative productive value (NPV) (95% CI 98-100 percent → what does this mean?). The prediction model had an area under the curve (AUC) for the receiver-operator curve (ROC) of 0.98 (implying a near perfect test performance). Similar results were noted in a retrospective score validation at a different institution evaluating 116 boys for an acute scrotum. Moreover, two subsequent prospective validations of the TWIST score (nearly 400 males assessed) continued to report high discrimination (AUC 0.82 - 0.95). In a study performed in a pediatric tertiary care emergency department, the TWIST score was most accurate in pubertal patients (Tanner stage ≥ 3). (Sheth et al., 2016)

Taken together, these studies support the practice of early surgical consultation for children in whom testicular torsion is strongly suspected based upon history and physical examination rather than imaging (e.g., high TWIST score of ≥5). Although TWIST score has demonstrated the ability to predict testicular torsion with a high NPV, further prospective studies are needed before it is exclusively used to diagnose testicular torsion (Bašković et al, 2019).

In most cases, the clinical findings will be equivocal for testicular torsion. In these patients, when available on-site, a color Doppler ultrasound of the scrotum should be obtained and emergency surgical consultation reserved for documented testicular torsion or continued diagnostic uncertainty (e.g., equivocal ultrasound findings). Demonstration of decreased testicular perfusion or twisting of the spermatic cord is consistent with testicular torsion. Decreased testicular perfusion also can be seen in some patients with a large hydrocele, abscess, hematoma, or scrotal hernia. A negative ultrasound (i.e., normal or increased testicular flow) may rarely occur in patients eventually diagnosed with testicular torsion, usually due to spontaneous detorsion and/or partial or intermittent torsion. The Doppler ultrasound can discern testicular and epididymal size, scrotal fluid, scrotal wall thickening, enlarged appendix testis, twisting of the spermatic cord, and arterial flow in the testis and epididymis. The reported sensitivity and specificity of Doppler ultrasound in the detection of
Testicular torsion ranges from 69-100% and 77-100%, respectively. The usefulness of Doppler ultrasound is limited in small prepubertal testes with lower blood flow.

An additional radiographic adjunct, is a nuclear scan which measures testicular perfusion. The reported sensitivity and specificity of scintigraphy are 100% and 97%, respectively. However, a nuclear scan takes several hours to perform and is typically not available quickly enough to permit timely operative detorsion and orchiopexy. For these reasons, Doppler ultrasound has supplanted the nuclear scan as the test of choice for testicular torsion.

**Lab tests:**
- Urinalysis
- Urine Culture
- GC/Chlamydia

**Radiologic studies:**
- STAT / Testicular Doppler US

**Clinical Management**

The diagnosis of testicular torsion, whether made clinically or radiographically, requires immediate consultation with a urologist followed by appropriate pain control. The treatment for a torsed testicle that remains viable involves surgical detorsion and fixation (orchiopexy). Orchiectomy is performed if the testicle is nonviable. The viability of a torsed testicle is dependent upon the duration and completeness of torsion. Typical rates of viability according to duration of torsion have been described as follows:

- Detorsion within 4 - 6 hours: 97-100% viability
- Detorsion after 12 hours: 20-61% viability
- Detorsion after 24 hours: 0-24% viability

Surgery should never be delayed on the assumption of nonviability based upon a clinical estimate of duration of torsion. Some patients with a prolonged period of symptoms may have had intermittent torsion or a partial torsion and testicles that are salvageable.

**Pharmacologic considerations:**

Pain management will be provided at the discretion/guidance of the EC physician.
**Johns Hopkins All Children’s Hospital**

**Emergency Center Acute Scrotal Pain Clinical Pathway**

### Inclusion Criteria:
- Acute onset of scrotal pain, intermittent scrotal pain, acute or intermittent abdominal pain, testicular trauma: blunt or penetrating, non-verbal with testicular swelling

### Exclusion Criteria:
- Patient with painless scrotal swelling

---

#### Outside Hosp Transfer:
- Transfer Center (TC) receives call
- TC contacts on-call Urologist (MD to MD report)
- Urologist accepts pt to EC
- Urologist may coordinate w/OR to schedule
- TC coordinates method of transport
- Pt placed on ER Tracking Board
- EC Team updated via secure messaging
- Pt arrival / admitted to EC

---

#### Suspicion for Testicular Torsion:
- Triaged as ESI Level 2
  - Age less than 30days old and/or trauma Consult Urology
- Nursing Protocol
  - NPO
  - UA & Urine Culture
  - If appropriate, consider GC/Chlamydia PCR
  - STAT Testicular Doppler US
  - May repeat if a transfer pt
  - STAT US are read by VRad or Radiologist
- Complete H&P
- Review pertinent risk factors
- Complete TWIST Scoring

### TWIST Scoring

<table>
<thead>
<tr>
<th>Findings</th>
<th>Points</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hard testes</td>
<td>2</td>
</tr>
<tr>
<td>Swelling</td>
<td>2</td>
</tr>
<tr>
<td>Nausea/vomiting</td>
<td>1</td>
</tr>
<tr>
<td>Absent cremasteric reflex</td>
<td>1</td>
</tr>
<tr>
<td>High-riding testis</td>
<td>1</td>
</tr>
</tbody>
</table>

#### Low Probability (TWIST 0-2)
- Cremasteric Reflex present
- Prehn’s Sign positive
- Pain Resolved
- Educate family on TT
- Maintain a low-threshold for further clinical workup for suspicious presentation
- Review Differential Diagnosis

#### Equivocal (TWIST 3-4)
- Non-verbal or difficult to assess child with concern for TT; continue NPO & pain management
- Review Differential Diagnosis

#### High Probability (TWIST ≥5)
- Abnormal lie of testicle
- Absent cremasteric reflex
- Severe Pain w/nausea & vomiting
- Consider manual detorsing when appropriate
- Consult Urology

---

#### Review Ultrasound Results

- US Negative or Consistent with Alternative Diagnosis
- US Positive for Testicular Torsion

#### Consider POC STI Testing

<table>
<thead>
<tr>
<th>Consider Alternative Diagnoses</th>
</tr>

<tr>
<td>Tumor / Trauma</td>
</tr>
<tr>
<td>Incarcerated Inguinal Hernia</td>
</tr>
</tbody>
</table>

*Hydrocele typically causes nontender swelling

---

#### Discharge Instructions / Follow-up
- Return precautions for possible intermittent torsion

---
**Emergency Center Management**

Patients classically present with an abrupt onset of severe testicular or scrotal pain, usually of less than 12 hours duration. Nearly 90 percent of patients may have associated nausea and vomiting. The pain can be isolated to the scrotum or may radiate to the lower abdomen. The pain is constant unless the testicle is torsing and detorsing. A typical presentation in children is a patient who is awaken with scrotal pain in the middle of the night or in the morning. Many boys report a previous episode of pain. However, a significant minority of males with testicular torsion may present with abdominal pain and not initially report testicular pain. This presentation emphasizes the importance of a complete genitourinary examination in all males with abdominal pain.

On physical examination, the scrotum may be edematous, indurated and erythematous and the affected testis is usually tender, swollen, and slightly elevated because of shortening of the cord from twisting. The testis may be lying horizontally, displacing the epididymis from its normal posterolateral position. A reactive hydrocele may also be present. The cremasteric reflex (elevation of the testis in response to stroking of the upper inner thigh) is absent in nearly all cases of torsion. However, this also may be absent in boys without torsion, particularly if they are younger than six months. Prehn reported that elevation of the scrotal contents relieves the pain in patients with epididymitis and aggravates or has no effect on the pain in patients with testicular torsion. However, Prehn sign is not a reliable distinguishing feature between torsion and other diagnoses in children.

**Admit to OR**

- Admission criteria includes positive results for testicular torsion (Admit to OR) per Urologist.
- If the patient is requiring multiple doses of analgesics and will be admitted, place in observation.

**Outcome Measures:**

- Time from triage to OR for testicular torsion
  - Appropriate triage of acute scrotal pain
  - Triage to US
  - Triage to Surgical Intervention
