Updated: July 2023
Owners: Courtney Titus, PA-C, Corey Fowler, PharmD

This pathway is intended as a guide for physicians, physician assistants, nurse practitioners and other healthcare providers. It should be adapted to the care of specific patient based on the patient’s individualized circumstances and the practitioner’s professional judgment.
Anaphylaxis Clinical Pathway

Rationale

This protocol was developed by a consensus group of JHACH emergency medicine providers, hospitalists, pharmacists and allergists, to standardize the management of children who present with anaphylaxis. It addresses the following clinical questions or problems:
1. When and how to recognize anaphylaxis
2. How to treat anaphylaxis in the acute setting
3. How long to observe patients treated for anaphylaxis
4. What medications should be prescribed on discharge for a patient treated for anaphylaxis
5. When to consider admission for further treatment and observation

Anaphylaxis Background and Diagnostic Criteria

Anaphylaxis is defined by the World Allergy Organization as “a serious allergic reaction that is rapid in onset and might cause death.” Anaphylaxis is a clinical diagnosis. The National Institute of Allergy and Infectious Diseases developed the clinical criteria for anaphylaxis diagnosis in 2004 and was subsequently adapted by the World Allergy Organization. They have been studied and found to have 97% sensitivity and 82% specificity in diagnosing anaphylaxis.

Potential anaphylactic reaction: ANAPHYLAXIS is highly likely when ONE of the following 3 criteria is fulfilled within minutes to 2 – 3 hours following possible allergen exposure.

- **CRITERIA 1** - Acute onset of an illness with involvement of the skin, mucosal tissue, or both (e.g., generalized hives, pruritis or flushing, swollen lip-tongue-uvula) AND AT LEAST ONE OF THE FOLLOWING:
  - Respiratory compromise (wheezing, shortness of breath, cough, stridor, hypoxemia, unable to speak, retractions, or flaring)
  - Reduced systolic blood pressure by ≥ 30% or associated symptoms of end-organ dysfunction (e.g., delayed capillary refill, syncope, altered mental status)
  - Persistent GI symptoms (e.g., significant abdominal pain and/or significant vomiting)

- **CRITERIA 2** - TWO OR MORE of the following that occur rapidly after exposure to a LIKELY ALLERGEN for the patient:
  - Involvement of the skin-mucosal tissue, (e.g., generalized hives, pruritis or flushing, swollen lip tongue-uvula)
  - Respiratory compromise (wheezing, shortness of breath, cough, stridor, hypoxemia, unable to speak, retractions, or flaring)
  - Reduced systolic blood pressure by ≥ 30% of pre-treatment baseline or associated symptoms of end-organ dysfunction (e.g., delayed capillary refill, syncope, altered mental status)
  - Persistent GI symptoms (e.g., significant abdominal pain and/or significant vomiting)

- **CRITERIA 3** - Reduced blood pressure by ≥ 30% of pre-treatment baseline after exposure to KNOWN ALLERGEN for the patient
Johns Hopkins All Children’s Hospital
Anaphylaxis Emergency Center Clinical Pathway

Does the patient meet the criteria for anaphylaxis?

Recline the patient or place them in a position of comfort and if applicable, stop the administration of the causative agent

Administer IM EPINEPHrine to the anterolateral thigh:

- < 7.5 kg = 0.01 mg/kg/dose – EPINEPHrine 1 mg/mL vial
- 7.5 – < 30 kg = 0.15 mg/dose – EpiPen®
- ≥ 30 kg = 0.3 mg/dose – EpiPen®

Insert a peripheral IV

Give 10 – 15 L O₂ via facemask if sats are < 90% or the patient is in respiratory distress
If there is evidence of impending airway obstruction, immediately intubate the patient
Consider obtaining a tryptase level (within 1 to 4 hours after symptom onset)

Is patient responding to EPINEPHrine? (blood pressure, perfusion improving)

Does the patient have risk factors for recurrence/severe anaphylaxis?
- History of a biphasic or severe reaction
- Progression of/persistent symptoms
- History of severe asthma
- Hypotension
- Requires > 1 EPINEPHrine dose
- Requires fluid bolus
- Medication trigger
- Delayed EPINEPHrine administration

No

Observe in the EC for 4 – 6 hours

Admit to the Hospitalists for observation

Has the patient had recurrent symptoms?

No

Provide education regarding auto-injector administration and risk of biphasic reactions
Arrange follow up with PCP and Allergy/Immunology

Discharge Medication:
EPINEPHrine auto-injector x2
Discharge the patient home

Yes

Manage as described to the right

Does the patient have continued cardiopulmonary instability (e.g., hypotension)?

Yes

Start IV EPINEPHrine infusion at 0.1 mcg/kg/minute, titrated to effect (max 1 mcg/kg/minute)
Consider intubating the patient
Continue repeat normal saline (NS) bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions ≥ 30% from baseline
If the patient is taking beta-blockers and is not responding to EPINEPHrine, consider administering glucagon (< 20 kg = 0.5 mg/dose; ≥ 20 kg = 1 mg/dose)

No

Admit to the hospitalist team for continued observation and management as needed

Transfer to PICU
Consider alternative diagnosis

Yes

Recline the patient or place them in a position of comfort and if applicable, stop the administration of the causative agent.

Administer IM EPINEPHrine to the anterolateral thigh:

- $< 7.5$ kg = $0.01$ mg/kg/dose – EPINEPHrine 1 mg/mL vial
- $7.5 - < 30$ kg = $0.15$ mg/dose – EpiPen JR®
- $\geq 30$ kg = $0.3$ mg/dose – EpiPen®

Main OCC St. Petersburg: Call Code Blue
Other OCC locations: Call 911

Give 10 – 15 L O₂ via facemask if sats are $< 90\%$ or patient is in respiratory distress

Insert a peripheral IV

Does the patient meet the criteria for anaphylaxis?

No

Yes

Monitor vitals for 5 minutes or until Code Team/EMS arrives

$\geq 5$ minutes since EPINEPHrine administration

Has Code Team/EMS arrived?

No

Patient responding to EPINEPHrine? (blood pressure, perfusion improving)

Yes

Assist with transfer

No

Repeat IM EPINEPHrine doses every 5 minutes as needed up to 3 times

Administer normal saline (NS) bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline

For shortness of breath, wheezing, dyspnea, respiratory distress not resolved after EPINEPHrine, give albuterol ($< 20$ kg: $2.5$ mg/dose; $\geq 20$ kg: $5$ mg/dose)

Administer PO/IV cetirizine/diphenhydramINE as needed for cutaneous manifestations or pruritis not resolved after EPINEPHrine administration

Monitor vitals every 5 minutes until Code Team/EMS arrives

This pathway is intended as a guide for physicians, physician assistants, nurse practitioners and other healthcare providers. It should be adapted to the care of specific patient based on the patient’s individualized circumstances and the practitioner’s professional judgment.
**Anaphylaxis Inpatient Clinical Pathway**

**Does the patient meet the criteria for anaphylaxis?**

- **No**
  - Consider alternative diagnosis

- **Yes**
  - Recline the patient or place them in a position of comfort and if applicable, stop the administration of the causative agent
  - Administer IM EPINEPHrine to the anterolateral thigh:
    - $< 7.5$ kg = 0.01 mg/kg/dose – EPINEPHrine 1 mg/mL vial
    - $7.5 – < 30$ kg = 0.15 mg/dose – EpiPen JR®
    - $30 \geq$ kg = 0.3 mg/dose – EpiPen®
  - **Medical/Surgery Floors**: Call Code Blue and prepare transfer to PICU
  - **Intensive Care Units**: Continue to treat or call Code Blue for rapidly progressing symptoms
  - Give 10 – 15 L \(O_2\) via facemask if sats are $< 90\%$ or patient is in respiratory distress
  - Insert a peripheral IV
  - Monitor vitals every 5 minutes for 10 minutes
  - **Yes**
    - Patient responding to EPINEPHrine? (blood pressure, perfusion improving)
    - Avoid sudden changes in position
    - Monitor vital signs Q1 hour
    - Watch for recurrent symptoms of anaphylaxis
    - Consider obtaining tryptase level (within 1 to 4 hours after symptom onset)
  - **No**
    - Does the patient meet the criteria for anaphylaxis?
      - **Yes**
        - 4 – 8 hours after EPINEPHrine administration:
          - Monitor vitals Q 2 hours, continue to monitor for recurrent signs of anaphylaxis
          - **Medications**: (see Table 1 for dosing)
            - Consider PO/IV cetirizine/diphenhydRAMINE for cutaneous manifestations or pruritis not resolved after EPINEPHrine administration
            - Consider albuterol PRN for shortness of breath, wheezing, dyspnea
      - **8 – 16 hours after EPINEPHrine administration:**
        - Monitor Vitals Q 4 hours, continue to monitor for recurrent signs of anaphylaxis
        - **Discharge Criteria:**
          - $> 12$ hours since last EPINEPHrine administration without recurrent symptoms
          - Patient is tolerating enteral intake
          - Education regarding auto-injector administration and the risk of biphasic reactions provided
          - Arrange follow-up with PCP and Allergy/Immunology
      - **Discharge Medications:**
        - EPINEPHrine auto-injector x2
      - **Does the patient have continued cardiopulmonary instability (e.g., hypotension)?**
        - **Yes**
          - 4 – 8 hours after EPINEPHrine administration:
            - 4 – 8 hours after EPINEPHrine administration:
              - Monitor vitals Q 2 hours, continue to monitor for recurrent signs of anaphylaxis
             - **Medications**: (see Table 1 for dosing)
               - Consider PO/IV cetirizine/diphenhydRAMINE for cutaneous manifestations or pruritis not resolved after EPINEPHrine administration
               - Consider albuterol PRN for shortness of breath, wheezing, dyspnea
             - **8 – 16 hours after EPINEPHrine administration:**
               - Monitor Vitals Q 4 hours, continue to monitor for recurrent signs of anaphylaxis
               - **Discharge Criteria:**
                 - $> 12$ hours since last EPINEPHrine administration without recurrent symptoms
                 - Patient is tolerating enteral intake
                 - Education regarding auto-injector administration and the risk of biphasic reactions provided
                 - Arrange follow-up with PCP and Allergy/Immunology

                 - 4 – 8 hours after EPINEPHrine administration:
                   - 4 – 8 hours after EPINEPHrine administration:
                     - 4 – 8 hours after EPINEPHrine administration:
                       - Monitor vitals Q 2 hours, continue to monitor for recurrent signs of anaphylaxis
                      - **Medications**: (see Table 1 for dosing)
                        - Consider PO/IV cetirizine/diphenhydRAMINE for cutaneous manifestations or pruritis not resolved after EPINEPHrine administration
                        - Consider albuterol PRN for shortness of breath, wheezing, dyspnea
                      - **8 – 16 hours after EPINEPHrine administration:**
                        - Monitor Vitals Q 4 hours, continue to monitor for recurrent signs of anaphylaxis
                        - **Discharge Criteria:**
                          - $> 12$ hours since last EPINEPHrine administration without recurrent symptoms
                          - Patient is tolerating enteral intake
                          - Education regarding auto-injector administration and the risk of biphasic reactions provided
                          - Arrange follow-up with PCP and Allergy/Immunology
                        - **Discharge Medications:**
                          - EPINEPHrine auto-injector x2
                - **No**
                  - **Repeat IM EPINEPHrine doses every 5 minutes as needed up to 3 times**
                  - **Repeat normal saline (NS) bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                  - **For shortness of breath, wheezing, dyspnea, and respiratory distress not resolved after EPINEPHrine, give albuterol (< 20 kg: 2.5 mg/dose; $> 20$ kg: 5 mg/dose)**
                  - **Consider PO/IV cetirizine/diphenhydRAMINE for cutaneous manifestations or pruritis not resolved after EPINEPHrine**
                  - **Consider dexAMETHasone for critically ill patients especially those with asthma, severe anaphylaxis, or other airway concerns**
                  - **Discharge Criteria:**
                    - Patient’s symptoms have resolved AND therapy has been deescalated
                  - **Discharge Medications:**
                    - EPINEPHrine auto-injector x2
                  - **Patient’s symptoms have resolved AND therapy has been deescalated**
                    - **Start IV EPINEPHrine infusion at 0.1 mcg/kg/minute, titrated to effect (max 1 mcg/kg/minute)**
                    - **Consider intubating the patient**
                    - **Continue repeat NS bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                    - **If the patient is taking beta-blockers and is not responding to EPINEPHrine, consider administering glucagon (< 20 kg: 0.5 mg/dose; $> 20$ kg: 1 mg/dose)**
                    - **Discharge Criteria:**
                      - Patient’s symptoms have resolved AND therapy has been deescalated
                    - **Discharge Medications:**
                      - EPINEPHrine auto-injector x2
                - **No**
                  - **Repeat IM EPINEPHrine doses every 5 minutes as needed up to 3 times**
                  - **Repeat normal saline (NS) bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                  - **For shortness of breath, wheezing, dyspnea, and respiratory distress not resolved after EPINEPHrine, give albuterol (< 20 kg: 2.5 mg/dose; $> 20$ kg: 5 mg/dose)**
                  - **Consider PO/IV cetirizine/diphenhydRAMINE for cutaneous manifestations or pruritis not resolved after EPINEPHrine**
                  - **Consider dexAMETHasone for critically ill patients especially those with asthma, severe anaphylaxis, or other airway concerns**
                  - **Discharge Criteria:**
                    - Patient’s symptoms have resolved AND therapy has been deescalated
                  - **Discharge Medications:**
                    - EPINEPHrine auto-injector x2
                    - **Patient’s symptoms have resolved AND therapy has been deescalated**
                      - **Start IV EPINEPHrine infusion at 0.1 mcg/kg/minute, titrated to effect (max 1 mcg/kg/minute)**
                      - **Consider intubating the patient**
                      - **Continue repeat NS bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                      - **If the patient is taking beta-blockers and is not responding to EPINEPHrine, consider administering glucagon (< 20 kg: 0.5 mg/dose; $> 20$ kg: 1 mg/dose)**
                      - **Discharge Criteria:**
                        - Patient’s symptoms have resolved AND therapy has been deescalated
                      - **Discharge Medications:**
                        - EPINEPHrine auto-injector x2
                      - **Patient’s symptoms have resolved AND therapy has been deescalated**
                        - **Start IV EPINEPHrine infusion at 0.1 mcg/kg/minute, titrated to effect (max 1 mcg/kg/minute)**
                        - **Consider intubating the patient**
                        - **Continue repeat NS bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                        - **If the patient is taking beta-blockers and is not responding to EPINEPHrine, consider administering glucagon (< 20 kg: 0.5 mg/dose; $> 20$ kg: 1 mg/dose)**
                        - **Discharge Criteria:**
                          - Patient’s symptoms have resolved AND therapy has been deescalated
                        - **Discharge Medications:**
                          - EPINEPHrine auto-injector x2
                          - **Patient’s symptoms have resolved AND therapy has been deescalated**
                            - **Start IV EPINEPHrine infusion at 0.1 mcg/kg/minute, titrated to effect (max 1 mcg/kg/minute)**
                            - **Consider intubating the patient**
                            - **Continue repeat NS bolus 20 mL/kg/dose (max 1 L/dose) as needed for persistent blood pressure reductions $\geq 30\%$ from baseline**
                            - **If the patient is taking beta-blockers and is not responding to EPINEPHrine, consider administering glucagon (< 20 kg: 0.5 mg/dose; $> 20$ kg: 1 mg/dose)**
                            - **Discharge Criteria:**
                              - Patient’s symptoms have resolved AND therapy has been deescalated
                            - **Discharge Medications:**
                              - EPINEPHrine auto-injector x2

Anaphylaxis Initial Treatment

The key management of anaphylaxis depends on early recognition and treatment with intramuscular EPINEPHrine. Patients presenting with anaphylaxis should be immediately triaged and prepared for EPINEPHrine administration. Intramuscular EPINEPHrine is the first line treatment for anaphylaxis (Class I, Level of Evidence A). EPINEPHrine has both alpha sympathomimetic and beta sympathomimetic actions which allow for peripheral vasoconstriction, increased cardiac output, and bronchodilation. It also inhibits the further release of inflammatory mediators from mast cells and basophils. EPINEPHrine is underused in the treatment of anaphylaxis in both prehospital and emergency center settings, most commonly because the caregiver did not recognize the severity of the reaction.

EPINEPHrine should be injected into the outer mid-thigh using a needled syringe with IV EPINEPHrine 1 mg/mL solution or via an auto-injector device. The recommended dose of EPINEPHrine:

- $< 7.5 \text{ kg} = 0.01 \text{ mg/kg/dose} – \text{EPINEPHrine 1 mg/mL vial}$
- $7.5 – < 30 \text{ kg} = 0.15 \text{ mg/dose} – \text{EpiPen Junior®}$
- $\geq 30 \text{ kg} = 0.3 \text{ mg/dose} – \text{EpiPen®}$

Repeated IM doses should be administered in the event of persisting respiratory or cardiovascular symptoms after 5 minutes for up to three doses (Class I, Level of Evidence B). The IM route allows for a peak EPINEPHrine level 8 minutes after administration on average compared to 34 minutes after subcutaneous administration. IM administration into the thigh results in higher peak plasma concentrations compared with administration into the upper arm. There are no absolute contraindications for the administration of EPINEPHrine. Complications from IM EPINEPHrine administration are very rare. Administration of EPINEPHrine should not be delayed while attempting to establish intravenous access.

Patients with suspected anaphylaxis should receive supplemental oxygen and full cardiorespiratory monitoring (Class IIa, Level of Evidence D). They should be placed in the supine position and should have two large bore IV lines inserted if there are any signs of cardiovascular compromise (Class I, Level of Evidence C). Patients with signs of cardiovascular involvement including tachycardia, hypotension, or delayed capillary refill should receive aggressive fluid resuscitation with 20 mL/kg/dose (max 1 L/dose) boluses of normal saline (NS) (Class I, Level of Evidence B). Boluses should be repeated as necessary to maintain cardiovascular stability. For any evidence of impending airway obstruction from angioedema, immediate intubation is indicated as delay could lead to complete obstruction (Class IIa, Level of Evidence C).

**Intravenous EPINEPHrine**

When EPINEPHrine is promptly injected IM, most patients respond to one, two, or at most three doses. For patients with inadequate response to IM EPINEPHrine and a bolus of IV normal saline (NS), a continuous infusion of EPINEPHrine should be administered, beginning at 0.1 mcg/kg/minute by an infusion pump (Class IIa, Level of Evidence C). This dose can be titrated up (max 1 mcg/kg/minute) or down according to blood pressure, cardiac rate and function, and oxygenation.

**Bronchospasm Treatment**

For bronchospasm resistant to IM EPINEPHrine, give nebulized albuterol 2.5 mg/dose for patients weighing less than 20 kg and nebulized albuterol 5 mg/dose for patients greater than or equal to 20 kg (Class IIa, Level of Evidence B).
Further Interventions if EPINEPHrine is Ineffective

For upper airway obstruction consider intubation (Class IIa, Level of Evidence C). For persistent hypotension continue IV normal saline (NS) boluses (Class I, Level of Evidence C). Patients on beta-blockers may not respond to EPINEPHrine and can be given IV glucagon (< 20 kg = 0.5 mg/dose; ≥ 20 kg = 1 mg/dose) (Class IIa, Level of Evidence B). Glucagon increases cyclic adenosine monophosphate intracellularly, independent of adrenergic receptors. It may therefore reverse refractory hypotension and bronchospasm. When administering glucagon, airway protection is necessary as emesis is a possible side effect.

Adjunctive Treatment with Antihistamines and Glucocorticoids

Although enteral antihistamines are the mainstay of treatment for minor allergic reactions, they are not appropriate for first-line management of anaphylaxis. Antihistamines have no role in treating or preventing respiratory or cardiovascular symptoms of anaphylaxis. The onset of action is not rapid enough for use. However, H₁ antagonists can be given as adjunctive therapy given their proven benefit with localized reactions such as urticaria. Consider giving cetirizine enterally or diphenhydRAMINE intravenously/intramuscularly in patients unable to tolerate enteral medications (Class IIb, Level of Evidence B). Also consider giving an H₂ antagonist such as famotidine for patients with gastrointestinal manifestations (Class IIb, Level of Evidence B).

Corticosteroids have a slow onset of action (4 – 6 hours) and are therefore not effective in the acute management of anaphylaxis. Giving corticosteroids does not have any significant effect on readmission for patients with allergic reactions. The benefit of corticosteroids in anaphylaxis has not been scientifically proven but it is common practice to treat with steroids as a secondary treatment (Class IIb, Level of Evidence B). Consider giving corticosteroids to critically ill patients especially those with asthma, severe anaphylaxis, or other airway concerns

### Laboratory Testing for Anaphylaxis

A serum tryptase level can be helpful when the diagnosis of anaphylaxis is unclear. Due to its short half-life, the test should be collected 1 to 4 hours after symptom onset. Although the turnaround time for serum tryptase is usually several days, the results are more beneficial for the diagnosis and future management of the patient. A normal serum tryptase level does not rule out anaphylaxis, especially in food-induced reactions (Class IIb, Level of Evidence C).

### Observation vs. Admission

Because most biphasic allergic reactions occur within the first 4 – 6 hours after the initial onset of symptoms, a reasonable length of time of observation of a patient treated for anaphylaxis is 4 – 6 hours (Class I, Level of Evidence B). Although rare, symptoms can recur up to 24 – 72 hours after initial presentation and caregivers should be counseled to monitor for such a recurrence. Patients who require repeated doses of EPINEPHrine, present with severe respiratory distress or hypotension, or experience a biphasic reaction during observation should be admitted to the hospital for observation (Class IIa, Level of Evidence B).
Discharge Instructions and Prescribing

Prescribe an EPINEPHrine autoinjector before discharge (Class I, Level of Evidence C). Teach the patient how to use the EPINEPHrine autoinjector using a trainer device. Refer all patients who present with anaphylaxis to Allergy/Immunology (Class Ia, Level of Evidence C). Children weighing 15 kg to less than 30 kg can receive a 0.15 mg dose of EPINEPHrine (EpiPen Junior®). Children weighing 30 kg or more can receive a 0.3 mg dose of EPINEPHrine (EpiPen®). For children weighing less than 15 kg, consider prescribing Auvi-Q® 0.1 mg EPINEPHrine autoinjector if possible. If the Auvi-Q® 0.1 mg EPINEPHrine autoinjector is not available, patients should receive a 0.15 mg dose of EPINEPHrine (EpiPen Junior®). The mainstay of management includes avoidance of triggers and provision of a rescue medication in the event of accidental reactions. Patients and families should be instructed to use their autoinjector when an allergic reaction is suspected and seek medical attention.

On discharge, prescribing a course of enteral steroids can be considered. Giving corticosteroids does not have any significant effect on readmission for patients with allergic reactions. The benefit of corticosteroids in anaphylaxis has not been scientifically proven but it is common practice to treat with steroids as a secondary treatment (Class IIb, Level of Evidence B). For example, dexamethasone 0.5 mg/kg/dose daily (max 16 mg/dose) for 1 additional day.

Outcome Measures

- Time to EPINEPHrine administration after presentation with symptoms
- Length of stay in the EC
- Length of stay in the hospital
- Percent of patients admitted to the hospital after presenting to EC with anaphylaxis
